```

## Combinatorics

### Binomial Coefficients

Number of ways to pick a multiset of size  $k$  from  $n$  elements:  $\binom{n+k-1}{k}$

Number of  $n$ -tuples of non-negative integers with sum  $s$ :  $\binom{s+n-1}{n-1}$ , at most  $s$ :  $\binom{s+n}{n}$

Number of  $n$ -tuples of positive integers with sum  $s$ :  $\binom{s-1}{n-1}$

Number of lattice paths from  $(0, 0)$  to  $(a, b)$ , restricted to east and north steps:  $\binom{a+b}{a}$

### Pascal Triangle

$$v_{r,c} = v_{r,c-1} \frac{r+1-c}{c}$$

$$x = r_0; y = 1; a_{r,c} = a_{r-1,c-1} \frac{++x}{++y}, r \geq r_0 + 2, c \geq 2$$

Line on a Pascal Triangle:  $c(n, k+1) = c(n, k) \times \frac{n-k}{k+1}$

### Log properties

$$\log(a^n) = n \times \log(a)$$

$$\log(n!) = \sum_{i=1}^n \log(i)$$

### Catalan numbers

$$C_n = \frac{1}{n+1} \binom{2n}{n}. C_0 = 1, C_n = \sum_{i=0}^{n-1} C_i C_{n-1-i}. C_{n+1} = C_n \frac{4n+2}{n+2}.$$

$$C_0, C_1, \dots = 1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862, 16796, 58786, 208012, 742900, \dots$$

$C_n$  is the number of: properly nested sequences of  $n$  pairs of parentheses; rooted ordered binary trees with  $n+1$  leaves; triangulations of a convex  $(n+2)$ -gon.

### Derangements

Number of permutations of  $n = 0, 1, 2, \dots$  elements without fixed points is 1, 0, 1, 2, 9, 44, 265, 1854, 14833, ... Recurrence:  $D_n = (n-1)(D_{n-1} + D_{n-2}) = nD_{n-1} + (-1)^n$ . Corollary: number of permutations with exactly  $k$  fixed points is  $\binom{n}{k} D_{n-k}$ .

### Bell numbers

$B_n$  is the number of partitions of  $n$  elements.  $B_0, \dots = 1, 1, 2, 5, 15, 52, 203, \dots$

$$B_{n+1} = \sum_{k=0}^n \binom{n}{k} B_k = \sum_{k=1}^n S_{n,k}. \text{ Bell triangle: } B_r = a_{r,1} = a_{r-1,r-1}, a_{r,c} = a_{r-1,c-1} + a_{r,c-1}.$$

## Eulerian numbers

$E(n, k)$  is the number of permutations with exactly  $k$  descents ( $i : \pi_i < \pi_{i+1}$ ) / ascents ( $\pi_i > \pi_{i+1}$ ) / excedances ( $\pi_i > i$ ) /  $k + 1$  weak excedances ( $\pi_i \geq i$ ).  
Formula:  $E(n, k) = (k + 1)E(n - 1, k) + (n - k)E(n - 1, k - 1)$ .

## Burnside's lemma

The number of orbits under  $G$ 's action on set  $X$  :  $|X/G| = \frac{1}{|G|} \sum_{g \in G} |X_g|$ , where  $X_g = \{x \in X : g(x) = x\}$ . ("Average number of fixed points.") Let  $w(x)$  be weight of  $x$ 's orbit. Sum of all orbits' weights:  $\sum_{o \in X/G} w(o) = \frac{1}{|G|} \sum_{g \in G} \sum_{x \in X_g} w(x)$ .

## Number Theory

### Linear diophantine equation

$ax + by = c$ . Let  $d = \gcd(a, b)$ . A solution exists iff  $d|c$ . If  $(x_0, y_0)$  is any solution, then all solutions are given by  $(x, y) = (x_0 + \frac{b}{d}t, y_0 - \frac{a}{d}t), t \in \mathbb{Z}$ . To find some solution  $(x_0, y_0)$ , use extended GCD to solve  $ax_0 + by_0 = d = \gcd(a, b)$ , and multiply its solutions by  $\frac{c}{d}$ .

Linear diophantine equation in  $n$  variables:  $a_1x_1 + \dots + a_nx_n = c$  has solutions iff  $\gcd(a_1, \dots, a_n)|c$ . To find some solution, let  $b = \gcd(a_2, \dots, a_n)$ , solve  $a_1x_1 + by = c$ , and iterate with  $a_2x_2 + \dots = y$ .

### Chinese Remainder Theorem

System  $x \equiv a_i \pmod{m_i}$  for  $i = 1, \dots, n$  with pairwise relatively prime  $m_i$  has a unique solution modulo  $M = m_1m_2\dots m_n$  :  $x = a_1b_1\frac{M}{m_1} + \dots + a_nb_n\frac{M}{m_n} \pmod{M}$ , where  $b_i$  is modular inverse of  $\frac{M}{m_i}$  modulo  $m_i$ .

System  $x \equiv a \pmod{m}, x \equiv b \pmod{n}$  has solutions iff  $a \equiv b \pmod{g}$ , where  $g = \gcd(m, n)$ . The solution is unique modulo  $L = \frac{mn}{g}$ , and equals:  $x \equiv a + T(b - a)m/g \equiv b + S(a - b)n/g \pmod{L}$ , where  $S$  and  $T$  are integer solutions of  $mT + nS = \gcd(m, n)$ .

## Extended GCD

```
//return x, y such a * x + b * y = gcd(a, b)
pair<int, int> gcd_extended(int a, int b){
    /*Use only if negative numbers are used as parameters
    if (a < 0){
        pair<int, int> p = gcd_extended(-a, b);
        p.first = -p.first;
        return p;
    }
    if (b < 0){
        pair<int, int> p = gcd_extended(a, -b);
        p.second = -p.second;
        return p;
    }
    */

    int x = 1, y = 0;
    int nx = 0, ny = 1;
```

```
    while (b){
        int q = a / b;
        x -= q * nx; swap(x, nx);
        y -= q * ny; swap(y, ny);
        a -= q * b; swap(a, b);
    }

    return mp(x, y);
}

//Reurn a inverse mod b
//gcd(a, b) must be 1
int mod_inv(int a, int b){
    return (gcd_extended(a, b).first + b) % b;
}
```

$$a^{-1}(\text{mod } n) = a^{\phi(n)-1}$$

$$n \text{ prime} \rightarrow a^{-1}(\text{mod } n) = a^{n-2}$$

## Prime-counting function

$\pi(n) = |\{p \leq n : p \text{ is prime}\}|$ .  $n/\ln(n) < \pi(n) < 1.3n/\ln(n)$ .  $\pi(1000) = 168$ ,  $\pi(10^6) = 78498$ ,  $\pi(10^9) = 50847534$ .  $n$ -th prime  $\approx n \ln(n)$ .

## Fast Sieve (Números primos)

```
const unsigned MAX = 1000000020/60, MAX_S = sqrt(MAX/60);

unsigned w[16] = {1, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 49, 53, 59};
unsigned short composite[MAX];
vector<int> primes;

void sieve(){
    unsigned mod[16][16], di[16][16], num;
    for (int i = 0; i < 16; i++)
        for (int j = 0; j < 16; j++){
            di[i][j] = (w[i]*w[j])/60;
            mod[i][j] = lower_bound(w, w + 16, (w[i]*w[j])%60) - w;
        }

    primes.push_back(2); primes.push_back(3); primes.push_back(5);
```

```
memset(composite, 0, sizeof composite);
for (unsigned i = 0; i < MAX; i++)
    for (int j = (i==0); j < 16; j++){
        if (composite[i] & (1<<j)) continue;
        primes.push_back(num = 60*i + w[j]);

        if (i > MAX_S) continue;
        for (unsigned k = i, done = false; !done; k++){
            for (int l = (k==0); l < 16 && !done; l++){
                unsigned mult = k*num + i*w[l] + di[j][l];
                if (mult >= MAX) done = true;
                else composite[mult] |= 1<<mod[j][l];
            }
        }
    }
}
```

## Miller-Rabin's primality test

```
int fastpow(int base, int d, int n){
    int ret = 1;
    for (int64 pow = base; d > 0; d >>= 1, pow = (pow * pow) % n)
        if (d & 1)
            ret = (ret * pow) % n;
    return ret;
}

bool miller_rabin(int n, int base){
    if (n <= 1) return false;
    if (n % 2 == 0) return n == 2;

    int s = 0, d = n - 1;
    while (d % 2 == 0) d /= 2, ++s;

    int base_d = fastpow(base, d, n);
```

```
if (base_d == 1) return true;
int base_2r = base_d;

for (int i = 0; i < s; ++i){
    if (base_2r == 1) return false;
    if (base_2r == n - 1) return true;
    base_2r = (int64)base_2r * base_2r % n;
}

return false;
}

bool isprime(int n){
    if (n == 2 || n == 7 || n == 61) return true;
    return miller_rabin(n, 2) && miller_rabin(n, 7) && miller_rabin(n, 61);
}
```

Given  $n = 2^r s + 1$  with odd  $s$ , and a random integer  $1 < a < n$ . If  $a^s \equiv 1 \pmod{n}$  or  $a^{2^j s} \equiv -1 \pmod{n}$  for some  $0 \leq j \leq r - 1$ , then  $n$  is a probable prime.

## Pollard- $\rho$ (Fatorização Int.)

```
int64 pollard_r, pollard_n;

int64 f(int64 val){ return (val*val + pollard_r) % pollard_n; }
int64 myabs(int64 a){ return a >= 0 ? a : -a; }

int64 pollard(int64 n){
    srand(unsigned(time(0)));
    pollard_n = n;

    int64 d = 1;
    do{
```

```
        d = 1;
        pollard_r = rand() % n;

        int64 x = 2, y = 2;
        while (d == 1)
            x = f(x), y = f(f(y)), d = __gcd(myabs(x-y), n);
    } while (d == n);

    return d;
}
```

Choose random  $x_1$ , and let  $x_{i+1} = x_i^2 \pmod n$ . Test  $\gcd(n, x_{2^k+i} - x_{2^k})$  as possible  $n$ 's factors for  $k = 0, 1, \dots$ . Expected time to find a factor:  $O(\sqrt{m})$ , where  $m$  is smallest prime power in  $n$ 's factorization. That's  $O(n^{1/4})$  if you check  $n = p^k$  as a special case before factorization.

## Fermat primes

A Fermat prime is a prime of form  $2^{2^n} + 1$ . The only known Fermat primes are 3, 5, 17, 257, 65537. A number of form  $2^n + 1$  is prime only if it is a Fermat prime.

## Perfect numbers

$n > 1$  is called perfect if it equals sum of its proper divisors and 1. Even  $n$  is perfect iff  $n = 2^{p-1}(2^p - 1)$  and  $2^p - 1$  is prime (Mersenne's). No odd perfect numbers are yet found.

## Carmichael numbers

A positive composite  $n$  is a Carmichael number ( $a^{n-1} \equiv 1 \pmod n$  for all  $a : \gcd(a, n) = 1$ ), iff  $n$  is square-free, and for all prime divisors  $p$  of  $n$ ,  $p - 1$  divides  $n - 1$ .

## Number/sum of divisors

```
//funcao sigma
//Soma dos divisores de n
int sigma(int n){
    int ans = 1;

    for (int i = 0; primes[i] * primes[i] <= n; i++){
        if (n % primes[i] == 0){
            int v = primes[i];

            while (n % primes[i] == 0){
                v *= primes[i];
                n /= primes[i];
            }
        }
    }
}
```

$$\tau(p_1^{a_1} \dots p_k^{a_k}) = \prod_{j=1}^k (a_j + 1).$$

$$\sigma(p_1^{a_1} \dots p_k^{a_k}) = \prod_{j=1}^k \frac{p_j^{a_j+1} - 1}{p_j - 1}.$$

```
    }

    ans *= (v - 1) / (primes[i] - 1);
}

if (n > 1)
    ans *= n + 1;

return ans;
}
```

## Euler's phi function

```
int phi(int n){
    int ans = n;

    for (int i = 0; primes[i] * primes[i] <= n; i++){
        if (n % primes[i] == 0){
            ans /= primes[i];
            ans *= primes[i] - 1;

            while (n % primes[i] == 0) n /= primes[i];
        }
    }
}
```

```
    }

    if (n > 1){
        ans /= n;
        ans *= n - 1;
    }

    return ans;
}
```

$$\phi(n) = |\{m \in \mathbb{N}, m \leq n, \gcd(m, n) = 1\}|.$$

$$\phi(mn) = \frac{\phi(m)\phi(n)\gcd(m,n)}{\phi(\gcd(m,n))}.$$

$$\phi(p^a) = p^{a-1}(p - 1).$$

$$\sum_{d|n} \phi(d) = \sum_{d|n} \phi\left(\frac{n}{d}\right) = n.$$

## Euler's Theorem

$$a^{\phi(n)} \equiv 1 \pmod{n}, \text{ if } \gcd(a, n) = 1.$$

## Wilson's Theorem

$p$  is prime iff  $(p-1)! \equiv -1 \pmod{p}$

## Mobius function

$$\mu(1) = 1.$$

$\mu(n) = 0$ , if  $n$  is not square free.

$\mu(n) = (-1)^s$ , if  $n$  is the product of  $s$  distinct primes.

Let  $f, F$  be functions on positive integers. If for all  $n \in \mathbb{N}$ ,  $F(n) = \sum_{d|n} f(d)$ , then  $f(n) = \sum_{d|n} \mu(d)F(\frac{n}{d})$ , and vice versa.

$$\phi(n) = \sum_{d|n} \mu(d) \frac{n}{d}.$$

$$\sum_{d|n} \mu(d) = 1.$$

If  $f$  is multiplicative, then  $\sum_{d|n} \mu(d)f(d) = \prod_{p|n} (1 - f(p))$ ,  $\sum_{d|n} \mu(d)^2 f(d) = \prod_{p|n} (1 + f(p))$

$f[i] = 1, f[p] = -1, f[j] * = (j \% (i * i) == 0) ? 0 : -1;$

## Legendre symbol

If  $p$  is an odd prime,  $a \in \mathbb{Z}$ , then  $(\frac{a}{p})$  equals 0, if  $p|a$ ; 1 if  $a$  is a quadratic residue modulo  $p$ ; and -1 otherwise. Euler's criterion:  $(\frac{a}{p}) = a^{(\frac{p-1}{2})} \pmod{p}$ .

## Jacobi symbol

If  $n = p_1^{a_1} \dots p_k^{a_k}$  is odd, then  $(\frac{a}{n}) = \prod_{i=1}^k (\frac{a}{p_i})^{a_i}$ .

## Primitive roots

If the order of  $g$  modulo  $m$  ( $\min n > 0 : g^n \equiv 1 \pmod{m}$ ) is  $\phi(m)$ , then  $g$  is called a primitive root. If  $\mathbb{Z}_m$  has a primitive root, then it has  $\phi(\phi(m))$  distinct primitive roots.  $\mathbb{Z}_m$  has a primitive root iff  $m$  is one of  $2, 4, p^k, 2p^k$ , where  $p$  is an odd prime. If  $\mathbb{Z}_m$  has a primitive root  $g$ , then for all  $a$  coprime to  $m$ , there exists unique integer  $i = \text{ind}_g(a)$  modulo  $\phi(m)$ , such that  $g^i \equiv a \pmod{m}$ .  $\text{ind}_g(a)$  has logarithm-like properties:  $\text{ind}(1) = 0$ ,  $\text{ind}(ab) = \text{ind}(a) + \text{ind}(b)$ .

If  $p$  is prime and  $a$  is not divisible by  $p$ , then congruence  $x^n \equiv a \pmod{p}$  has  $\gcd(n, p-1)$  solutions if  $a^{(p-1)/\gcd(n, p-1)} \equiv 1 \pmod{p}$ , and no solutions otherwise.

## Discrete log

Find  $x$  from  $a^x \equiv b \pmod{m}$ . Can be solved in  $O(\sqrt{m})$  time and space with a meet-in-the-middle trick. Let  $n = \lceil \sqrt{m} \rceil$ , and  $x = ny - z$ . Equation becomes  $a^{ny} \equiv ba^z \pmod{m}$ . Precompute all values that the RHS can take for  $z = 0, 1, \dots, n-1$ , and brute force  $y$  on the LHS, each time checking whether there's a corresponding value for RHS.

**Pythagorean triples**

Integer solutions of  $x^2 + y^2 = z^2$ . All relatively prime triples are given by:  $x = 2mn, y = m^2 - n^2, z = m^2 + n^2$  where  $m > n$ ,  $\gcd(m, n) = 1$  and  $m \not\equiv n \pmod{2}$ . All other triples are multiples of these. Equation  $x^2 + y^2 = 2z^2$  is equivalent to  $(\frac{x+y}{2})^2 + (\frac{x-y}{2})^2 = z^2$ .

**Postage stamps/McNuggets problem**

Let  $a, b$  be relatively-prime integers. There are exactly  $\frac{1}{2}(a-1)(b-1)$  numbers *not* of form  $ax + by (x, y \geq 0)$ , and the largest is  $(a-1)(b-1) - 1 = ab - a - b$ .

**Fermat's two-squares theorem**

Odd prime  $p$  can be represented as a sum of two squares iff  $p \equiv 1 \pmod{4}$ . A product of two sums of two squares is a sum of two squares. Thus,  $n$  is a sum of two squares iff every prime of form  $p = 4k + 3$  occurs an even number of times in  $n$ 's factorization.

## String Algorithms

### String Hash

```
#define MAXN 10000
#define BASE 33ULL
#define VALUE(c) ((c)-'a')

typedef unsigned long long int64;

int64 h[MAXN], pw[MAXN];

int64 calc_hash(int beg, int end){
    return h[end] - h[beg]*pw[end-beg];
}
```

### Prefix Function

```
void prefixfunction(string S){
    int N = SIZE(S);

    p[0] = p[1] = 0;
    FOR(i, 2, N){
        int j = p[i-1];
        while (S[i-1] != S[j]){
            if (j == 0){ j = -1; break; }
            j = p[j];
        }
        p[i] = ++j;
    }
}
```

### Manacher

```
void manacher(strind &ss){
    string s = "#";
    for (size_t i = 0, sz = ss.size(); i < sz; ++i){
        s += ss[i];

- First occurrence of string  $P = firstpos(v) - |P| + 1$ ;
- All occurrences: same as before, but must follow inverse suffix links and don't print clones.

**Burrows-Wheeler inverse transform**

Let  $B[1..n]$  be the input (last column of sorted matrix of string's rotations). Get the first column,  $A[1..n]$ , by sorting  $B$ . For each  $k$ -th occurrence of a character  $c$  at index  $i$  in  $A$ , let  $\text{next}[i]$  be the index of corresponding  $k$ -th occurrence of  $c$  in  $B$ . The  $r$ -th row of the matrix is  $A[r]$ ,  $A[\text{next}[r]]$ ,  $A[\text{next}[\text{next}[r]]]$ , ...

**Huffman's algorithm**

Start with a forest, consisting of isolated vertices. Repeatedly merge two trees with the lowest weights.

```

For any graph, if it has an even cycle, this graph is bipartite

**Euler's theorem**

For any planar graph,  $V - E + F = 1 + C$ , where  $V$  is the number of graph's vertices,  $E$  is the number of edges,  $F$  is the number of faces in graph's planar drawing, and  $C$  is the number of connected components. Corollary:  $V - E + F = 2$  for a 3D polyhedron.

**Vertex covers and independent sets**

Let  $M$ ,  $C$ ,  $I$  be a max matching, a min vertex cover, and a max independent set. Then  $|M| \leq |C| = N - |I|$ , with equality for bipartite graphs. Complement of an MVC is always a MIS, and vice versa. Given a bipartite graph with partitions  $(A, B)$ , build a network: connect source to  $A$ , and  $B$  to sink with edges of capacities, equal to the corresponding nodes' weights, or 1 in the unweighted case. Set capacities of the original graph's edges to the infinity. Let  $(S, T)$  be a minimum  $s - t$  cut. Then a maximum(-weighted) independent set is  $I = (A \cap S) \cup (B \cap T)$ , and a minimum(-weighted) vertex cover is  $C = (A \cap T) \cup (B \cap S)$ .

**Matrix-tree theorem**

Let matrix  $T = [t_{ij}]$ , where  $t_{ij}$  is the number of multiedges between  $i$  and  $j$ , for  $i \neq j$ , and  $t_{ii} = -deg_i$ . Number of spanning trees of a graph is equal to the determinant of a matrix obtained by deleting any  $k$ -th row and  $k$ -th column from  $T$ .

**Prufer code of a tree**

Label vertices with integers 1 to  $n$ . Repeatedly remove the leaf with the smallest label, and output its only neighbor's label, until only one edge remains. The sequence has length  $n - 2$ . Two isomorphic trees have the same sequence, and every sequence of integers from 1 and  $n$  corresponds to a tree. Corollary: the number of labelled trees with  $n$  vertices is  $n^{n-2}$ .

**Euler tours**

Euler tour in an undirected graph exists iff the graph is connected and each vertex has an even degree. Euler tour in a directed graph exists iff in-degree of each vertex equals its out-degree, and underlying undirected graph is connected. Construction:

```
doit(u):
    for each edge e = (u, v) in E, do: erase e, doit(v)
    prepend u to the list of vertices in the tour
```

## Stable marriage problem (Lobos Stark)

While there is a free man  $m$ : let  $w$  be the most-preferred woman to whom he has not yet proposed, and propose  $m$  to  $w$ . If  $w$  is free, or is engaged to someone whom she prefers less than  $m$ , match  $m$  with  $w$ , else deny proposal.

```
int prefList[430][430];
int status[830]; /* status[i] contains husband/wife of i, initially -1 */
map<int, string> rev_bib;

void stableMarriage(int n){
    FOR(i, 2*n) status[i] = -1; /* 0...n mens, n...2*n women */
    queue<int> singleM;
    FOR(i, n) singleM.push(i); /* Push all single men */

    /* While there is a single men */
    while (!singleM.empty()){
        int i = singleM.front();
        singleM.pop();
        FOR(j, n){
            /* if girl is single marry her to this man */
            int singleW = prefList[i][j];
            if (status[singleW] == -1){
                status[i] = singleW; /* set this girl as wife of i */
                status[singleW] = i; /* make i as husband of this girl */
                break;
            }
            else{
                int rank1, rank2; /* for holding priority of current */
```

```
                FOR(k, n){ /* husband and most preferable husband */
                    if (prefList[singleW][k] == status[singleW]) rank1 = k;
                    if (prefList[singleW][k] == i) rank2 = k;
                }
                /* if this girl j prefers current man i more than her present husband */
                if (rank2 < rank1){
                    status[i] = singleW; /* her wife of i */
                    int old = status[singleW];
                    status[old] = -1; /* divorce current husband */
                    singleM.push(old); /* add him to list of singles */
                    status[singleW] = i; /* set new husband for this girl */
                    break;
                }
            }
        }

        FOR(i, n){
            /* print each matching */
            cout << rev_bib[i] << "_" << rev_bib[status[i]] << endl;
        }
    }
}
```

## Stoer-Wagner (Corte mínimo - Fluxo)

Start from a set  $A$  containing an arbitrary vertex. While  $A \neq V$ , add to  $A$  the most tightly connected vertex ( $z \notin A$  such that  $\sum_{x \in A} w(x, z)$  is maximized.) Store cut-of-the-phase (the cut between the last added vertex and rest of the graph), and merge the two vertices added last. Repeat until the graph is contracted to a single vertex. Minimum cut is one of the cuts-of-the-phase.

```
/* Stoer-Wagner Min Cut on undirected graph */
```

```
#define MAXV 101
```

```
int grafo[MAXV][MAXV];
```

```
// v[i] representa o vertice original do grafo correspondente
// ao i-esimo vertice do grafo da fase atual do minCut e w[i]
// tem o peso do vertice v[i]..
```

```

```

```
    }
    return minimo;
```

```
}
```

## Erdos-Gallai theorem

A sequence of integers  $\{d_1, d_2, \dots, d_n\}$ , with  $n - 1 \geq d_1 \geq d_2 \geq \dots \geq d_n \geq 0$  is a degree sequence of some undirected simple graph iff  $\sum d_i$  is even and  $d_1 + \dots + d_k \leq k(k - 1) + \sum_{i=k+1}^n \min(k, d_i)$  for all  $k = 1, 2, \dots, n - 1$ .

### Dilworth's theorem

In any finite partially ordered set, the maximum number of elements in any antichain equals the minimum number of chains in any partition of the set into chains.

Dilworth's theorem characterizes the width of any finite partially ordered set in terms of a partition of the order into a minimum number of chains. An antichain in a partially ordered set is a set of elements no two of which are comparable to each other, and a chain is a set of elements every two of which are comparable. Dilworth's theorem states that there exists an antichain  $A$ , and a partition of the order into a family  $P$  of chains, such that the number of chains in the partition equals the cardinality of  $A$ . When this occurs,  $A$  must be the largest antichain in the order, for any antichain can have at most one element from each member of  $P$ . Similarly,  $P$  must be the smallest family of chains into which the order can be partitioned, for any partition into chains must have at least one chain per element of  $A$ . The width of the partial order is defined as the common size of  $A$  and  $P$ .

## Tarjan algorithm for articulation points (Vértice)

```
#define MAXN 111

int N;

    }
};
```

## Games

### Grundy numbers

For a two-player, normal-play (last to move wins) game on a graph  $(V, E)$ :  $G(x) = \text{mex}(\{G(y) : (x, y) \in E\})$ , where  $\text{mex}(S) = \min\{n \geq 0 : n \notin S\}$ .  $x$  is losing iff  $G(x) = 0$ .

### Sums of games

- Player chooses a game and makes a move in it. Grundy number of a position is xor of grundy numbers of positions in summed games.
- Player chooses a non-empty subset of games (possibly, all) and makes moves in all of them. A position is losing iff each game is in a losing position.
- Player chooses a proper subset of games (not empty and not all), and makes moves in all chosen ones. A position is losing iff grundy numbers of all games are equal.
- Player must move in all games, and loses if can't move in some game. A position is losing if any of the games is in a losing position.

### Misère Nim

A position with pile sizes  $a_1, a_2, \dots, a_n \geq 1$ , not all equal to 1, is losing iff  $a_1 \oplus a_2 \oplus \dots \oplus a_n = 0$  (like in normal nim.) A position with  $n$  piles of size 1 is losing iff  $n$  is odd.

}
```

## Geometry

### Pick's theorem

$I = A - B/2 + 1$ , where  $A$  is the area of a lattice polygon,  $I$  is the number of lattice points inside it, and  $B$  is the number of lattice points on the boundary. Number of lattice points minus one on a line segment from  $(0, 0)$  and  $(x, y)$  is  $\gcd(x, y)$ .

$$a \cdot b = a_x b_x + a_y b_y = |a| \cdot |b| \cdot \cos(\theta)$$

$$a \times b = a_x b_y - a_y b_x = |a| \cdot |b| \cdot \sin(\theta)$$

$$3D: a \times b = (a_y b_z - a_z b_y, a_z b_x - a_x b_z, a_x b_y - a_y b_x)$$

### Line

Line  $ax + by = c$  through  $A(x_1, y_1)$  and  $B(x_2, y_2)$ :  $a = y_1 - y_2$ ,  $c = x_2 - x_1$ ,  $c = ax_1 + by_1$ .

Half-plane to the left of the directed segment  $AB$ :  $ax + by \geq c$ .

Normal vector:  $(a, b)$ . Direction vector:  $(b, -a)$ . Perpendicular line:  $-bx + ay = d$ .

Point of intersection of  $a_1x + b_1y = c_1$  and  $a_2x + b_2y = c_2$  is  $\frac{1}{a_1b_2 - a_2b_1}(c_1b_2 - c_2b_1, a_1c_2 - a_2c_1)$ .

Distance from line  $ax + by + c = 0$  to point  $(x_0, y_0)$  is  $|ax_0 + by_0 + c| / \sqrt{a^2 + b^2}$ .

Distance from line  $AB$  to  $P$  (for any dimension):  $\frac{|(A-P) \times (B-P)|}{|A-B|}$ .

Point-line segment distance:

if  $(\text{dot}(B - A, P - A) < 0)$  return  $\text{dist}(A, P)$ ;

if  $(\text{dot}(A - B, P - B) < 0)$  return  $\text{dist}(B, P)$ ;

return  $\text{fabs}(\text{cross}(P, A, B) / \text{dist}(A, B))$ ;

### Projection

Projection of point  $C$  onto line  $AB$  is  $\frac{AB \cdot AC}{AB \cdot AB} AB$ .

Projection of  $(x_0, y_0)$  onto line  $ax + by = c$  is  $(x_0, y_0) + \frac{1}{a^2 + b^2}(ad, bd)$ , where  $d = c - ax_0 - by_0$ .

Projection of the origin is  $\frac{1}{a^2 + b^2}(ac, bc)$ .

### Segment-segment intersection

Two line segments intersect if one of them contains an endpoint of the other segment, or each segment straddles the line, containing the other segment ( $AB$  straddles line  $l$  if  $A$  and  $B$  are on the opposite sides of  $l$ .)

### Circle-circle and circle-line intersection

```

a = x2 - x1;    b = y2 - y1;    c = [(r1^2 - x1^2 - y1^2) - (r2^2 - x2^2 - y2^2)] / 2;
d = sqrt(a^2 + b^2);
if not |r1 - r2| <= d <= |r1 + r2|, return "no solution"
if d == 0, circles are concentric, a special case
// Now intersecting circle (x1,y1,r1) with line ax+by=c
Normalize line: a /= d; b /= d; c /= d;    // d=sqrt(a^2+b^2)
e = c - a*x1 - b*y1;
h = sqrt(r1^2 - e^2);    // check if r1<e for circle-line test
return (x1, y1) + (a*e, b*e) +/- h*(-b, a);

```

### Circle from 3 points (circumcircle)

Intersect two perpendicular bisectors. Line perpendicular to  $ax + by = c$  has the form  $-bx + ay = d$ . Find  $d$  by substituting midpoint's coordinates.

### Angular bisector

Angular bisector of angle  $ABC$  is line  $BD$ , where  $D = \frac{BA}{|BA|} + \frac{BC}{|BC|}$ .

Center of incircle of triangle  $ABC$  is at the intersection of angular bisectors, and is  $\frac{a}{a+b+c}A + \frac{b}{a+b+c}B + \frac{c}{a+b+c}C$  where  $a, b, c$  are lengths of sides, opposite to vertices  $A, B, C$ . Radius =  $\frac{2S}{a+b+c}$

### Counter-clockwise rotation around the origin

$(x, y) \rightarrow (x \cos \phi - y \sin \phi, x \sin \phi + y \cos \phi)$ .

90-degrees counter-clockwise rotation:  $(x, y) \rightarrow (-y, x)$ . Clockwise:  $(x, y) \rightarrow (y, -x)$ .

### 3D rotation

3D rotation by ccw angle  $\phi$  around axis  $n$ :  $r' = r \cos \phi + n(n \cdot r)(1 - \cos \phi) + (n \times r) \sin \phi$

### Plane equation from 3 points

$N \cdot (x, y, z) = N \cdot A$ , where  $N$  is normal:  $N = (B - A) \times (C - A)$ .

### 3D figures

Sphere: Volume  $V = \frac{4}{3}\pi r^3$ , surface area  $S = 4\pi r^2$

$$x = \rho \sin \theta \cos \phi, y = \rho \sin \theta \sin \phi, z = \rho \cos \theta, \phi \in [-\pi, \pi], \theta \in [0, \pi]$$

Spherical section: Volume  $V = \pi h^2(r - h/3)$ , surface area  $S = 2\pi r h$

Pyramid: Volume  $V = \frac{1}{3}hS_{base}$

Cone: Volume  $V = \frac{1}{3}\pi r^2 h$ , lateral surface area  $S = \pi r \sqrt{r^2 + h^2}$

### Area of a simple polygon

$\frac{1}{2} \sum_{i=0}^{n-1} (x_i y_{i+1} - x_{i+1} y_i)$ , where  $x_n = x_0, y_n = y_0$ . Area is negative if the boundary is oriented clockwise.

### Winding number

Shoot a ray from given point in an arbitrary direction. For each intersection of ray with polygon's side, add +1 if the side crosses it counterclockwise, and -1 if clockwise.

### Range Tree

```

```

## Integer Partitioning

```

/*
    Description: Template for calculating the number of ways of
                partitioning the integer N into M parts.

```

Complexity:  $O(N^2)$

Notes: A partition of a number N is a representation of  
N as the sum of positive integers  
e.g.  $5 = 1+1+1+1+1$

The number of ways of partitioning an integer N  
into M parts is equal to the number of ways of  
partitioning the number N with the largest element  
being of size M. This is best seen with a Ferres-  
Young diagram:  
Suppose  $N = 8, M = 3$ :

```

4 = * * * *
   3 = * * *
     1 = *
   3 2 2 1

```

By transposition from rows to columns, this equality  
can be seen.

```

P(N, M) = P(N-1, M-1) + P(N-M, M)
P(0, M) = P(N, 0) = 0
P(N, 1) = 1

```

```

*/

## Edit Distance (with path recovery)

```

/*
   Description: Computes the edit distance for two strings. Namely
               this involves certain costs for Replacement,
               Insertions and Deletions. Given these costs, and
               two words, this program calculates the minimum cost
               way to transform the first string to the second. An
               added bonus is the PathRecovery() subroutine, which
               prints out exactly what happens step by step.

   Complexity:  $O(N^2)$  where  $N$  is the size of the larger of the two
               strings

   Notes: Some modifications need to be made in order to fix
           path recovery.
*/

## Edit distance between two strings

```

/*
 * The edit distance between two strings is determined based on
 * three possible actions:
 * 1) Change: changes one symbol in a string to match
 * a symbol in another string.
 * 2) Insert: inserts a symbol into a string at a position
 * corresponding to the same symbol in the other string.
 * 3) Delete: deletes a symbol from one string that doesn't
 * appear in the other string.
 *
 * There is a simple (very simple) example for path recovery. Should
 * you wish to implement your own, the parts of this code pertaining to
 * path recovery are centralized in the procedure path_recovery().
 *
 * This algorithm uses dynamic programming and is O(nm). In theory,
 * ie. not in this implementation, it is not necessary to store the
 * entire table, only two columns need to be stored at any given step
 * if all that is desired is to compute the edit distance. In this
 * case, it takes O(m) space. NOTE: If this is done, path recovery
 * is NOT possible.
 *
 * If you don't like this algorithm, another possibility is to use
 * Dijkstra's algorithm for shortest paths in the grid graph.
 *
 * Two possible edit distance configurations are coded below, and
 * the vast multitude remaining are left as an exercise for the
 * reader.
 *
 * - int edit_general(char *A, char *B, int change, int insert, int delete);
 * Specify the strings and assign weights for changing, inserting,
 * and deleting.
 *
 * - int edit_equal(char *A, char *B);
 * Specify the strings. Changing, inserting, and deleting all
 * carry unit weight.
 *
 */

```

```

* - int edit_no_change(char *A, char *B);
* Specify the strings. Changing is not allowed. To represent
* this to the algorithm, the weight of changing is set to greater
* than the sum of insert and delete--in this case, three.

```

## Miscellaneous

### Subsets of a subset in $O(3^n)$

```
for (int i=0; i < (1<<n); ++i) {
    for (int i2 = i; i2 > 0; i2 = (i2-1) & i) {
    }
}
```

### Fractional Cascading

Given  $k$  sorted sequences  $S$ , find first element  $\geq q$  in all  $k$  sequences in  $O(\log n + k)$ .

We will generate  $k$  modified sequences  $M$ . Every element of a sequence  $M_i$  will have two indexes associated with it: it's supposed index in  $S_i$  rounding to the largest option, and it's supposed index in  $M_{i+1}$ .

Starting in  $M_k$  ( $M_k = S_k$ , all the second indexes are zero, and the first indexes are the actual indexes in  $S_i$ ), for every  $M_i$  do:

Insert in  $M_{i-1}$  all the elements in odd positions of  $M_i$

In every insertion maintain the index in  $M_i$  of the last inserted element, and the index of the element currently being inserted. With that information, find out the second indexes of the elements between the last inserted and the currently being inserted.

The first indexes of all the original elements are initialized with their actual indexes, and the first indexes of the inserted elements are initialized with  $\min(\text{index of first original element before the inserted one} + 1, \text{sequence size} - 1)$  or if the element is being inserted in position 0, the index is 0

With that information, do a binary search in the first sequence ( $M_0$ ), with that you'll find the answer to the query in  $S_0$  being  $S_{0\text{element.first}}$ , and then you go to the position  $\text{element.second}$  of  $M_1$ , and check if element in position  $\text{element.second}-1$  is  $\geq q$ , if it is true, the element you're looking for is  $\text{element.second}-1$ , otherwise it's  $\text{element.second}$ . The answer to the current sequence will be in the index that is in the element in the found index ( $\text{element.second}-1$  or  $\text{element.second}$ ) .first. Repeat the process until you find the last answer in  $M_k$

### Warnsdorff's heuristic for knight's tour

At each step choose a square which has the least number of valid moves that the knight can make from there.

### Optimal BST - Knuth Optimization

$$\text{root}[i, j-1] \leq \text{root}[i, j] \leq \text{root}[i+1, j].$$

### Flow-shop scheduling (Johnson's problem)

Schedule  $N$  jobs on 2 machines to minimize completion time.  $i$ -th job takes  $a_i$  and  $b_i$  time to execute on 1st and 2nd machine, respectively. Each job must be first executed on the first machine, then on second. Both machines execute all jobs in the same order. Solution: sort jobs by key  $a_i < b_i ? a_i : (\infty - b_i)$ ,

i.e. first execute all jobs with  $a_i < b_i$  in order of increasing  $a_i$ , then all other jobs in order of decreasing  $b_i$ .

## Generate de Bruijn sequence

```
string seq;

int pw(int b,int a){
    int ans = 1;
    while ( a ){
        if (a&1) ans *= b;
        b *= b;
        a /= 2;
    }
    return ans;
}

void debruijn( int n, int k ){
    seq = "";
    char s[n];
    if ( n == 1 ){
        for ( int i = 0; i < k; i++ )
            seq += char('0'+i);
    }

    else{
        for ( int i = 0; i < n-1; i++ )
            s[i] = k-1;

        int kn = pw(k, n-1);
        char nxt[kn]; memset(nxt, 0, sizeof(nxt));
        kn *= k;
        for ( int h = 0; h < kn; h++ ){
            int m = 0;
            for ( int i = 0; i < n-1; i++ ){
                m *= k;
                m += s[(h+i)%(n-1)];
            }
            seq += char('0'+nxt[m]);
            s[h%(n-1)] = nxt[m];
            nxt[m]++;
        }
    }
}
```

A  $k$ -ary De Bruijn sequence  $B(k, n)$  of order  $n$  is a cyclic sequence of a given alphabet  $A$  with size  $k$  for which every possible subsequence of length  $n$  in  $A$  appears as a sequence of consecutive characters exactly once.

## Josephus

```
int live[MAXN];
void josephus( int n, int m ){ // n people, m-th get killed
    live[1] = 0;
    for( int i = 2; i <= n; i++ )
        live[i] = (live[i-1]+(m%i))%i;
}
```

## LIS $O(n \log n)$ (Maior Seq. Crescente)
